Review 2 - Literature Review and Gaps Finding:

[1] Park and Bae (2015) compared multiple data-mining techniques for house-price prediction and showed that machine-learning models can capture relationships between property characteristics and prices. The study demonstrates the usefulness of selecting relevant property features when building predictive models.

[2] Antipov and Pokryshevskaya (2012) investigated machine-learning approaches for apartment price prediction. Their work showed that property attributes and location-related variables can provide useful information for estimating real-estate prices.

[3] Bin et al. (2020) studied machine-learning methods for real-estate valuation and highlighted the importance of combining property characteristics with location information. The findings support the use of supervised learning for automated property-price estimation.

[4] Dimopoulos and Gavalas (2021) examined machine-learning approaches for real-estate price prediction and emphasized that model performance depends on the quality and representation of input features. Appropriate preprocessing and feature engineering are therefore important.

[5] Choy and Ho (2008) applied artificial neural networks to property valuation and demonstrated that nonlinear models can be useful for estimating residential property values. This suggests that relationships between house characteristics and prices may not always be adequately represented by simple linear models.

[6] Limsombunchai (2004) compared regression and artificial-neural-network approaches for house-price prediction. The study showed that machine-learning approaches can provide competitive predictive performance and highlighted the importance of evaluating models using suitable prediction-error measures.

Overall Findings

The literature indicates that machine-learning regression can support house-price prediction by learning relationships between property characteristics, location and selling price. Model performance depends strongly on data quality, relevant feature selection, preprocessing and the choice of regression algorithm. A key gap is the need for a practical and understandable prediction system that compares multiple models and identifies which property features contribute most to the predicted price.
